This chapter presents in an editorial manner the main concepts regarding the defensive role of interferons (IFNs) during virus infections. The chapter begins with a description of the background and individual mechanisms of action of IFNs and ends with an integrated hypothesis concerning how the individual mechanisms may interact during an *in vivo* infection. The format calls primarily for citing reviews in which more specific references can be found [1-12].

Background

Interferon (IFN) was discovered 25 years ago by Isaacs and Lindenmann, who showed that fluids from virus-infected cell cultures contained a protein that could protect cells against a wide variety of viruses. Since then, at least three antigenically different proteins or glycoproteins have been found in humans and mice to possess the functional characteristics of IFNs but have major differences in antigenicity and amino acid sequences. These IFNs have been named alpha, beta, and gamma and they all react with cells to induce various degrees of antiviral activity along with other biological functions; including antitumor action, immunoregulatory action, cell growth inhibition, alteration of cell membranes, macrophage activation, enhancement of cytotoxicity of lymphocytes, influence on subsequent production of interferon, and hormone-like activation of cells.
